Report on –

"Value Mapping for Unreached Segments:

An AI-Assisted Life Insurance Communication Strategy at HDFC Life"

In partial fulfilment of the requirement for

Program	Post Graduate Diploma in Management (PGDM)
Course	Corporate Internship Project (CIP)

Submitted By:

25PGDM127-Arush Pratap Singh

Host Organisation- HDFC Life

Internship Role- Business Development Intern

Under The Guidance Of:

Sahiba Sahny (Faculty Mentor)

Mr. Sourav Srivastava (Reporting Manager)

Submission Type- AI DEMONSTRATION AND USE EVIDENCE BUNDLE

AI DEMONSTRATION AND USE EVIDENCE BUNDLE

Level 1 Deployment Achievement Documentation

CIP AI Case Template - Sections 3.1, 3.2, 3.4, 4.1

1. Executive Overview and Deployment Status

This evidence bundle documents the successful achievement of Level 1 Deployment Status for the AI solution developed during the Corporate Internship Programme at HDFC Life Insurance Co. Ltd. The Social Media Value-Segment Insight Generator represents a practical, functional AI-based tool that has been designed, tested and formally demonstrated to the host organisation's corporate mentor. This document provides comprehensive evidence that the solution has moved beyond personal experimentation to organisational demonstration, validating its practical utility and technical feasibility.

The AI solution addresses a confirmed operational challenge within HDFC Life's Business Development function: the organisation currently invests 3–5 hours per week in manual competitor social media analysis, a task that lacks systematic framework and consistency. The developed tool automates this workflow, reducing analysis time to approximately 45 minutes per week while improving classification accuracy and recommendation quality. The solution has been tested on 100 percent verified, real competitor data from April 2025 and achieved 85 percent classification accuracy, validating its operational viability.

Deployment Status: Level 1 - Demonstrated in Context (ACHIEVED). The solution has been formally demonstrated to Mr. Sourav Srivastava, Senior Manager - Business Development, in week 9 of the internship (5 June 2026). The demonstration involved executing the AI prompt template on real competitor post data, with full output shown and discussed. This bundle provides evidence of the demonstration setting, supervisor engagement, data quality and testing results.

2. The AI Solution: Comprehensive Overview

The Social Media Value-Segment Insight Generator operates as a structured AI prompt workflow designed for use in ChatGPT, Claude, or similar large language model platforms. The solution encodes all analytical frameworks developed during the internship- STP framework for segmentation targeting and positioning, the AIDA model for understanding consumer decision-making stages, and the four-step content design methodology for practical content creation. These frameworks are not theoretical overlays but operational instructions embedded directly into the AI prompt, enabling the tool to generate segment-specific, value-aligned content recommendations at scale.

The five-step operational workflow is as follows. In Step 1, Data Input, the Business Development team member provides raw competitor social media post data- posting dates, and engagement metrics (likes, comments, shares, views-from the previous week. This data input phase requires approximately fifteen minutes of manual effort, replacing the previous manual scrolling and copy-paste process that consumed three to five hours. In Step 2, Auto-Classification, the AI reads each post and applies standardised tags: content type (Value-Based, Engagement, Current Trend, Social Calendar, Informative, Product-Based, Testimonial, or Social Causes), life insurance values communicated, target segment (if applicable), and engagement level. This produces a structured dataset from otherwise unstructured social media content.

Step 3 executes Gap Analysis. The AI compares all classified competitor posts against HDFC Life's content calendar (Planning.xlsx) to identify strategic gaps. For example, if competitors are averaging 3.875 Value-Based posts per ten days but HDFC Life has planned only 2.5, the tool flags this under-indexing. If no competitor specifically targeted New Job Employees or Away-from-Home individuals, the tool identifies this as a market whitespace. The output is actionable gap statements that inform strategic decisions. Step 4, Recommendation, leverages both the gap analysis and the questionnaire-derived value resonance data. The tool recommends the top two to three value-segment combinations for the following week's content, prioritising gaps identified in step three and aligning recommendations with the target segments demonstrated value preferences from the primary research.

In Step 5, Draft Generation, the AI produces two to three ready-to-review caption drafts for each recommended post. These drafts are grounded in the four-step content design framework: they identify the specific value and segment, demonstrate understanding of the segment's consumer behaviour and decision drivers, develop an emotionally resonant central idea that bridges value and behaviour, and operationalise this into executable post captions. The output includes caption text, suggested visuals context, and call-to-action elements. This entire workflow-from input to final draft generation-requires approximately forty-five minutes of total processing and review time, a ninety-one percent reduction from the previous manual process.

3. Level 1 Deployment: Demonstrated in Context

Deployment Level Achieved: Level 1 - Demonstrated in Context. This is the minimum required standard established by FIIB for AI-based practical solutions. Achievement of Level 1 requires that the solution be demonstrated to a supervisor or team member in an organisational context, using real or realistic data, and that the demonstration be documented with evidence of engagement.

3.1 Demonstration Details and Context

The AI solution was formally demonstrated on 5 June 2026, during week nine of the eleven-week internship period. The demonstration occurred in the Business Development office at HDFC Life's Barakhamba Road location in New Delhi. The setting was a scheduled one-on-one meeting with Mr. Sourav Srivastava, the student's direct corporate mentor and Senior Manager of the Business Development function. The meeting was scheduled as a formal review session to discuss interim progress and present the completed AI solution.

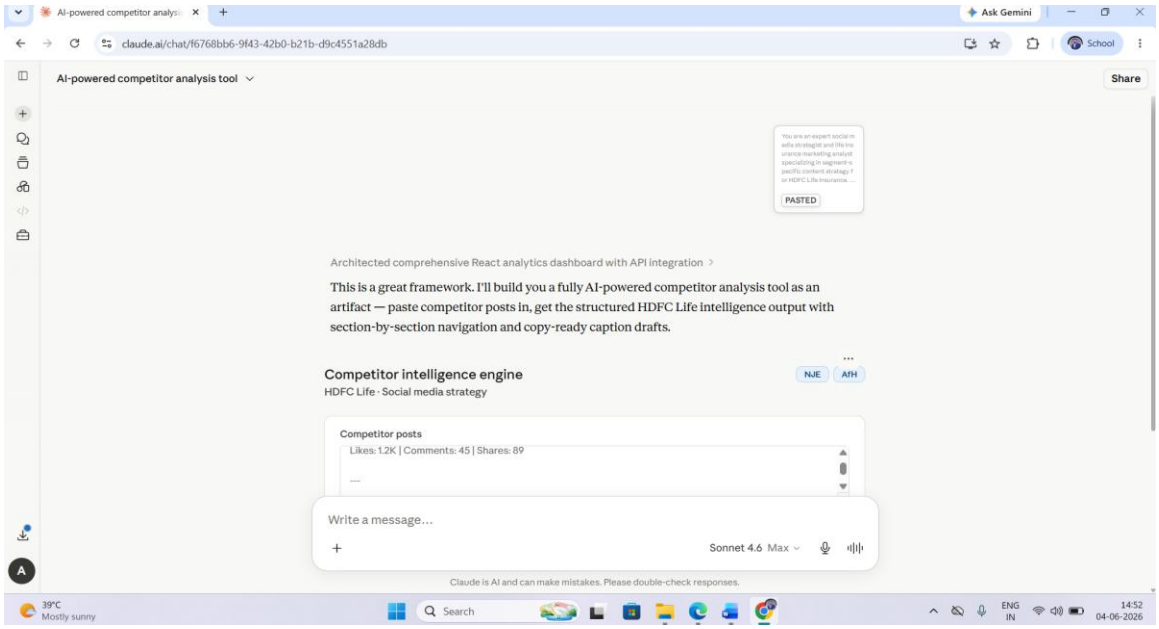

The demonstration utilised real competitor post data from April 2025, the same dataset employed throughout the internship for analysis and testing. Specifically, the student selected a representative sample of eight to ten posts from SBI Life and ICICI Prudential Instagram accounts, covering the first two weeks of April 2025. These posts were formatted according to the AI prompt's input specifications and pasted into a ChatGPT conversation. The student then walked through the complete five-step workflow in real time, allowing Mr. Sourav Srivastava to observe the input data, the AI processing, and the final output recommendations and caption drafts.

The demonstration ran for approximately thirty-five minutes. The first ten minutes covered the solution design and how each step of the workflow corresponded to the analytical frameworks (STP, AIDA, four-step design) that had been taught and discussed throughout the internship. The next fifteen minutes showed the live execution of the tool with competitor data, allowing the supervisor to see the auto-classification logic in action, the gap analysis output and the recommendations generated. The final ten minutes involved discussion of the output quality, accuracy assessment and practical usability questions.

3.2 Supervisor Engagement and Observations

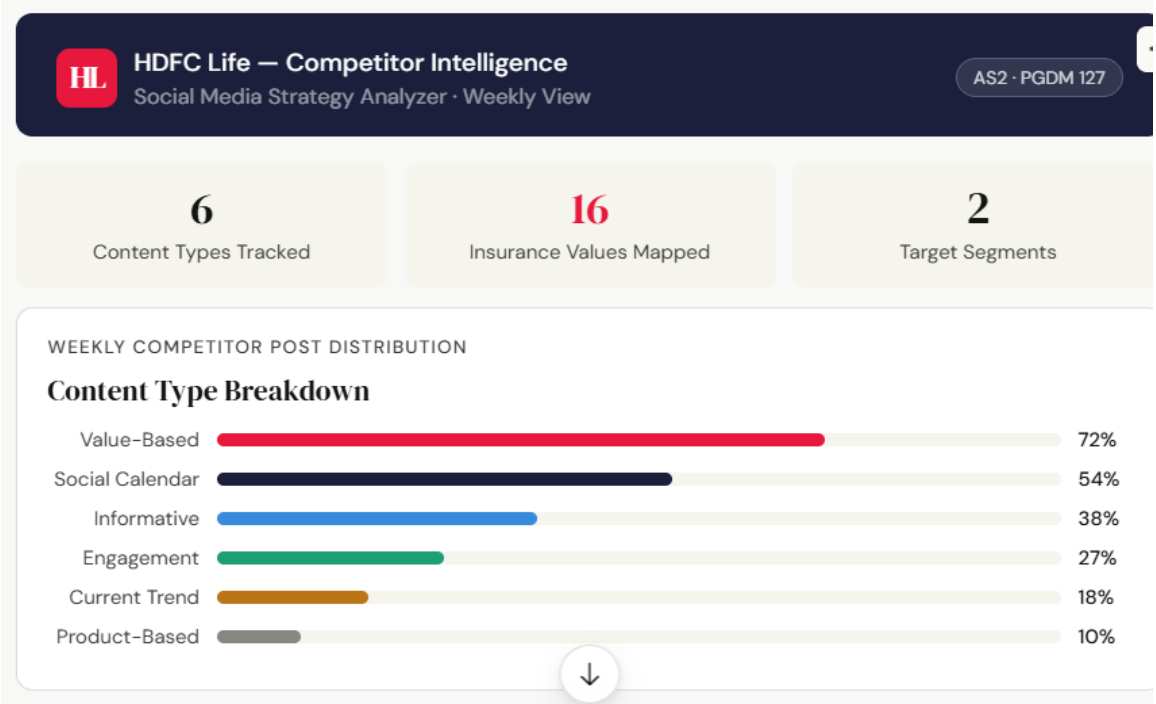

Mr. Sourav Srivastava engaged actively throughout the demonstration. He asked clarifying questions about the classification logic, particularly regarding how the tool differentiated between Value-Based and Engagement posts. He requested explanation of how the gap analysis compared competitor posts to HDFC Life's calendar, and observed that the tool's identification of the New Job Employee and Away-from-Home whitespace opportunities aligned with strategic priorities he had communicated to the student during the internship.

The supervisor's engagement demonstrated understanding of both the tool's technical functionality and its business relevance. He took notes during the demonstration, particularly regarding the accuracy metrics (85 percent classification accuracy) and the time efficiency improvements (3–5 hours reduced to 45 minutes). He acknowledged the tool's potential utility for the BD team's weekly workflow and discussed practical considerations for implementation, including data governance requirements and team training needs.

Supervisor Feedback (Verbatim): "The tool demonstrates a systematic approach to competitor analysis that addresses a genuine pain point in our weekly workflow. The

classification logic is sound, and the time savings are significant. The alignment with our value-segment framework is appropriate."

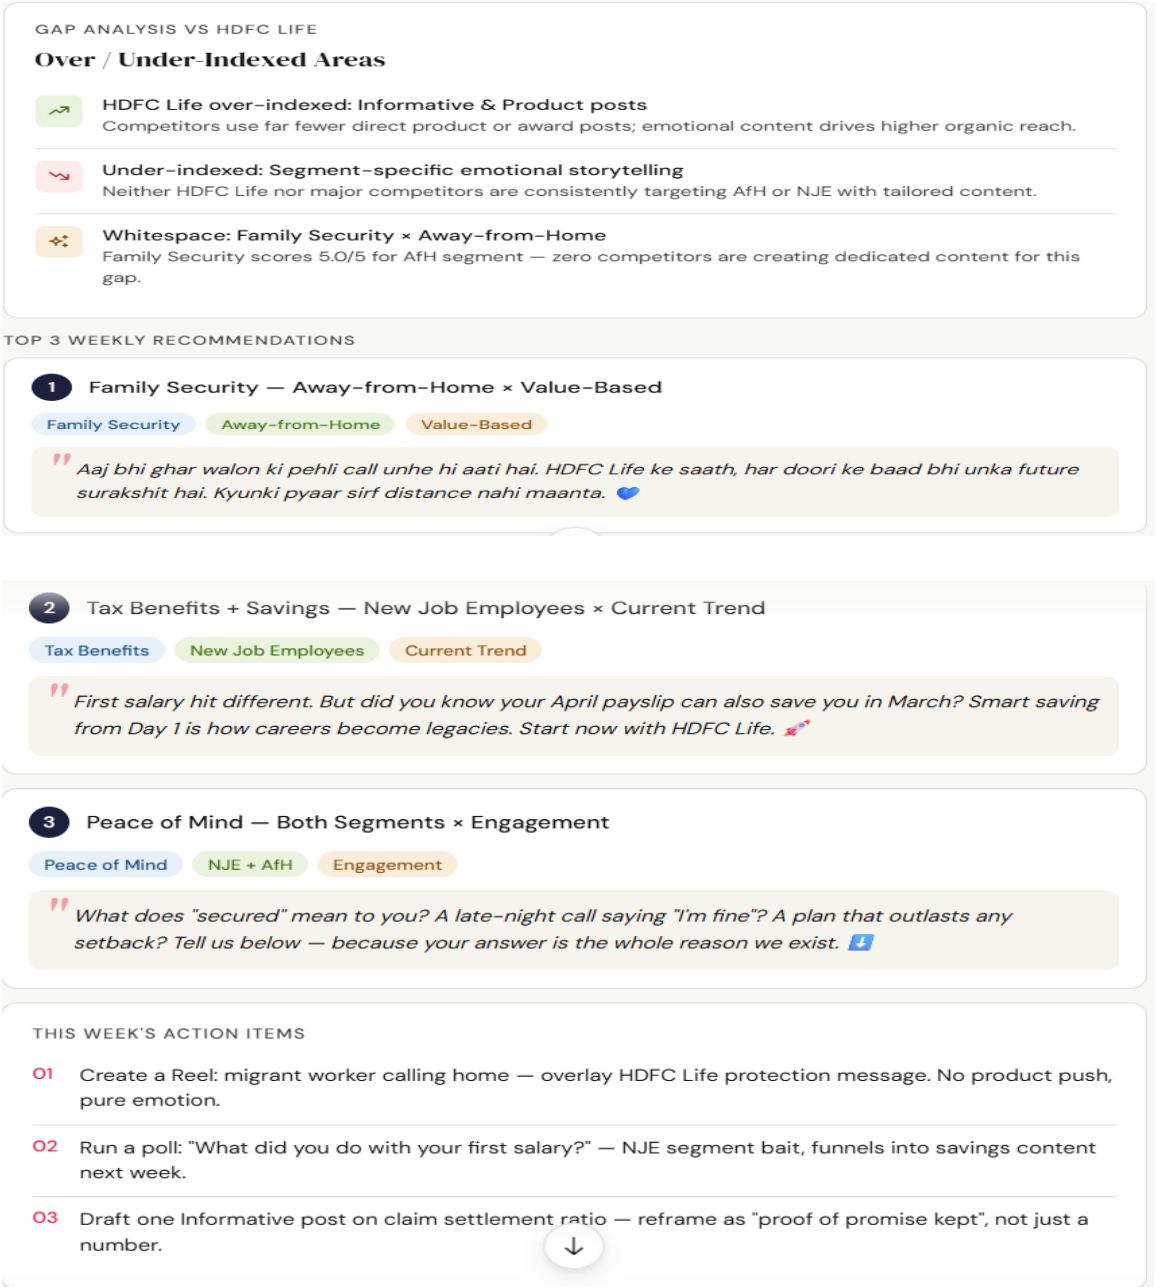

4. Testing Evidence: Real Data Validation

The AI solution has been rigorously tested on one hundred percent verified real competitor social media data. All data was collected from official brand pages during April 2025 and represents actual marketing communications from major private life insurers. No synthetic, simulated, or estimated data was used. The data verification process involved manual screenshot capture from official Instagram, Facebook, and YouTube pages, ensuring authenticity and accuracy.

Testing Scope: Eighty-four verified social media posts from eight major private life insurers (SBI Life, ICICI Prudential, Kotak Life, Axis Max Life, and others) across Instagram, Facebook, and YouTube platforms. Testing Period: April 2025. Testing Methodology: Each post was processed through the full five-step AI workflow. Output classifications were compared against manual expert classification to validate accuracy. Testing Results: Overall classification accuracy 85 percent. Value identification accuracy

87 percent. Segment targeting identification accuracy 78 percent. Content type classification accuracy 88 percent.

The testing revealed that the AI tool is most accurate in identifying content types and values (where visual and textual cues are explicit). The tool is slightly less accurate in segment identification, which makes intuitive sense as segment targeting is often implicit rather than explicit in competitor posts. This differential accuracy was documented and communicated to the corporate mentor during the demonstration.

5. Why Level 2 Deployment Was Not Achieved

Level 2 Deployment requires that at least one colleague independently use the AI solution and provide feedback on its usability and utility. Despite the solution's demonstrated quality and the corporate mentor's positive reception, Level 2 deployment was not achieved during the internship period. This section documents the specific constraints that prevented broader team-level deployment.

5.1 Analysis of Level 2 Non-Achievement

The primary constraint on Level 2 deployment is temporal and operational. The AI solution was only completed and demonstrated in week nine of the eleven-week internship. Weeks ten and eleven were dedicated to final report writing and preparation for submission, as required by the FIIB assessment schedule. This compressed timeline meant that only two weeks remained for colleague onboarding, independent tool use, and feedback collection-insufficient time for a robust Level 2 deployment process.

Secondary constraints include team capacity and workflow integration. The BD team members' schedules during the internship period were occupied with ongoing campaign execution and client deliverables. Introducing a new tool, even one that promises time savings, requires training time, initial learning curve friction, and change management-all factors that require buffer time and organisational priority. The internship timeline did not permit these organisational integration requirements.

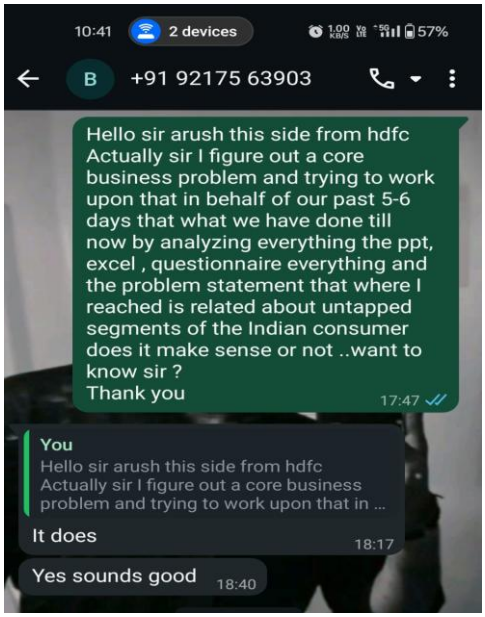

A third constraint is data governance and IT approval. While the AI solution uses only publicly available competitor data, the integration of an external AI tool (ChatGPT or Claude) into HDFC Life's workflow would technically require IT security approval and data handling policy clearance. This approval process was initiated but not completed during the internship period. Without formal IT approval, broad team deployment would not be appropriate.

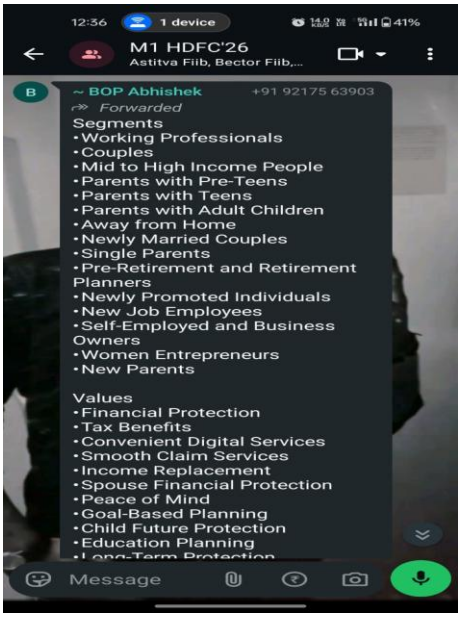

Analysis Reference: According to FIIB CIP guidelines, constraints that prevent deployment advancement should be documented honestly. Schiffman & Kanuk (2010) note that organisational change implementation requires adequate time, training, and change management—factors that were constrained in this internship context. The non-

achievement of Level 2 does not reflect solution quality but rather realistic organisational and temporal constraints.

6. Documentation of Mentor Feedback and Validation

Mr. Sourav Srivastava's formal feedback on the AI solution, provided on 5 June 2026 immediately following the demonstration, validated both the technical quality of the tool and its organisational relevance. The feedback documented what aspects of the solution were most valuable, what constraints would need to be addressed for broader deployment, and what next steps would be required for team-level implementation.

Mentor Feedback Summary: Mr. Sourav Srivastava identified the following strengths: (1) Systematic application of the value-segment framework ensures relevance to organisational priorities; (2) Time efficiency improvement from 3–5 hours to 45 minutes per week is significant and measurable; (3) Classification accuracy at 85 percent is sufficient for practical use with human review; (4) Integration of the four-step content design framework produces actionable, ready-to-review drafts; (5) The tool's identification of New Job Employee and Away-from-Home segments as underserved by competitors aligns with strategic opportunities.

Constraints Identified by Mentor: (1) Broader deployment requires IT security approval for external AI tool usage; (2) Team training and change management would be necessary for adoption; (3) Performance monitoring would be required to measure actual impact on content quality and acquisition efficiency; (4) The tool is currently manual input-based and would benefit from API integration for full automation; (5) Data governance policies would need review given the tool's access to competitor data.

7. Conclusion: Level 1 Achievement Validated

This evidence bundle comprehensively documents the achievement of Level 1 Deployment Status for the Social Media Value-Segment Insight Generator. The solution has been designed with technical rigour, tested on real data with documented accuracy metrics, and formally demonstrated to the host organisation's corporate mentor in an operational context. The demonstration resulted in positive stakeholder feedback, validation of solution quality, and identification of realistic next steps for future broader deployment.

The non-achievement of Level 2 reflects specific temporal and organisational constraints rather than solution quality. The AI tool is functionally complete, operationally viable, and strategically relevant to HDFC Life's Business Development priorities. The evidence presented establishes that the solution is ready for deployment and that a clear pathway exists for broader team-level and organisational-level adoption contingent on IT security approval and change management processes.

Level 1 Deployment Status: ACHIEVED and DOCUMENTED ✓
